Wpf datagridtemplatecolumn.celltemplate style. Wpf listview celltemplate style. Wpf gridviewcolumn.celltemplate style.

CellTemplate Property (Column) In This Topic Gets or sets the template used to display the contents of a cell that is not in editing mode. Syntax The CellTemplate and CellEditingTemplate properties work like the equivalent ones in the Microsoft DataGrid for Silverlight/WPF. They can be defined in XAML and are used to create the visual elements that represent the cells in the column. CellTemplate creates cells in regular mode and CellEditingTemplate creates cells in edit mode. Note that in most cases you should specify a Binding for the column even if it has custom templates. The templates are used to show and edit the values on the grid, but the column binding is still used when getting data values for other purposes including clipboard and export support. Example The XAML below creates a column with custom templates for cell display and editing (notice that in addition to the templates, the XAML specifies a Binding for the column). See Also The WPF DataGrid is the goto grid-like control for desktop development. Create the columns first. Testing One Two Three The code above says: "For each item in the DataGrid create a Button that has the text shown". This is the result. These buttons have implicit binding to the Text shown inside the button tag. Similar to innerText in HTML this property is called 'content' instead. In all of our DataGrid columns we prefer the DataGridTemplateColumn approach. We do this to take advantage of premade user controls like the Button. The current theme is applied as a result. Binding to a Collection of Items The data we show, in our case, is that of an ObservableCollection which is recommended in WPF land. The binding can be done in the code behind as follows: var content = new ObservableCollection<new ProcessList()>(); processListDataGrid.ItemsSource = content; By setting the items source directly we are providing the data the grid needs. However, nothing showed until we told each column the property name to show. Stop Process For first timers, none of this is intuitive, and even for those returning to WPF there's plenty of stumbling blocks. Keep in mind that our data model defines the fields. Data Model public class ProcessInfo { public string id { get; set; } public string windowtitle { get; set; } public string processname { get; set; } } Don't forget the getters and setters! Where did the data come from? public class ProcessList : List { public ProcessList() { var items = Process.GetProcesses().Where(item => item.MainWindowTitle != string.Empty || item.ProcessName.Contains("chromedriver")).ToList(); items.ForEach(item => { this.Add(new ProcessInfo() { id = item.Id.ToString(), windowtitle = item.MainWindowTitle, processname = item.ProcessName, }); }); } Of course, the System.Diagnostics.Process class! The Button Click Handler private async void OnKillProcess(object sender, RoutedEventArgs e) { Button btn = (Button)sender; int id = int.Parse(btn.Tag.ToString()); await Task.Run(() => { var proc = Process.GetProcessById(id); proc.Kill(); }); this.RefreshView(); } Async first to stop any GUI lag. It's all simple once we know how, it's easily remembered if we log how to do it on Dev.to. JW2021 WPF UserControl Process I am using a WPF DataGrid where one of the columns has a requirement to show an "Edit" hyperlink if the row is editable - this is indicated by a boolean flag in the backing model for the row. I was able to achieve this using a DataGridTemplateColumn - no problems. However an additional requirement on the entire row is not to show any highlights when the row is selected (this is a blue background by default). I have been able to achieve this on other columns by defining the DataGridCellStyle with a transparent background, e.g. where DataGridCellStyle is defined as follows: ... However the column in question, a DataGridTemplateColumn, does not offer a "CellStyle" attribute which I can use for turning off selection highlights. So my question is how to set the cell style when using a DataGridTemplateColumn? Here's my implementation of the column which satisfies the first requirement (i.e. showing an "Edit" hyperlink if the row is editable): Thanks. Namespace: DevExpress.Xpf.Grid.Assembly: DevExpress.Xpf.Grid.v22.1.Core.dll Declaration public DataTemplate CellTemplate { get; set; } Public Property CellTemplate As DataTemplate Type Description DataTemplate Defines the contents of column cells. To use multiple cell templates within the same column, define a custom CellTemplateSelector instead of the CellTemplate property. If both properties are specified, the template returned by the template selector has a higher priority. If the template selector returns null, the template specified by the CellTemplate property is used. Data Binding Cell elements contain EditGridCellData objects in their DataContext. Use the following binding paths to access cell values, columns, and ViewModel properties: Value - access the current cell value; Column - access the current column; RowData.Row.[YourPropertyName] - access a property of an object from the ItemsSource collection; Data.[FieldName] - access column values in Server Mode, access unbound column values; View.DataContext.[YourPropertyName] - access a property in a grid's ViewModel. The code sample below shows how to use a Button within grid cells and bind its Visibility property to an unbound column value: Hide View Example: How to build binding paths within WPF Grid control cells Data Binding in Detail Grid In master-detail mode, the master row is the data context for the detail GridControl. The View.DataContext.[YourPropertyName] binding path allows you to access the master row's properties. We recommend that you set a custom editor in the cell template as follows: The editor is a BaseEdit descendant. The editor's Name property is set to PART.Editor. This technique has the following advantages: Binds the editor's value to the source field specified by the ColumnBase.FieldName or ColumnBase.Binding properties. Full keyboard navigation support. Input validation support. For more information, refer to the Input Validation topic. Removes the editor's border to adjust the appearance for in-place use. The code snippet below shows a basic CellTemplate with TextEdit: To change how the GridControl binds the cell editor to a source property, use the ColumnBase.Binding property: Use the editor's EditValue property if you need to change how the GridControl handles the editor's value and specify a custom binding. The immediate posting functionality is not supported in this scenario: You can use non-BaseEdit cell editors in the CellTemplate to display and edit data. This method has the following limitations: You cannot use the PART.Editor method and you should bind the editor's value. Non-DevExpress editors do not use lightweight templates that are designed to improve performance. The GridControl does not remove the editor's borders to adjust the appearance of in-place use. You need to handle events to process user actions such as focusing and keyboard navigation: Search text highlighting is not supported. Immediate Posting is not supported. Conditional Formatting is not supported. Input Validation is not supported. Data Processing and EditSettings When you use the CellTemplate, the editor specified in the EditSettings property is ignored. However, the EditSettings value affects the formatting settings, data processing (sorting, grouping, filtering, summary calculation), and export. Events in CellTemplate The GridControl utilizes virtualization to improve its performance. Virtualization reuses row, cell, and column visual elements, and changes their properties and data context. Do not handle events related to changes in the EditValue, Text, Value, SelectedItem and other value-related properties to avoid issues related to virtualization. Instead, use CellValueChanged and CellValueChanging. Refer to this KB article for more information: How to avoid problems with the DXGrid virtualization mechanism. See Also
